

## RSA Algorithm in Cryptography

Read

Discuss(20+)

Courses

**RSA algorithm** is an asymmetric cryptography algorithm. Asymmetric actually means that it works on two different keys i.e. **Public Key** and **Private Key**. As the name describes that the Public Key is given to everyone and the Private key is kept private.

**An example of asymmetric cryptography:**

1. A client (for example browser) sends its public key to the server and requests some data.
2. The server encrypts the data using the client's public key and sends the encrypted data.
3. The client receives this data and decrypts it.

Since this is asymmetric, nobody else except the browser can decrypt the data even if a third party has the public key of the browser.

**The idea!** The idea of RSA is based on the fact that it is difficult to factorize a large integer. The public key consists of two numbers where one number is a multiplication of two large prime numbers. And private key is also derived from the same two prime numbers. So if somebody can factorize the large number, the private key is compromised. Therefore encryption strength totally lies on the key size and if we double or triple the key size, the strength of encryption increases exponentially. RSA keys can be typically 1024 or 2048 bits long, but experts believe that 1024-bit keys could be broken in the near future. But till now it seems to be an infeasible task.

Let us learn the mechanism behind the RSA algorithm :>> Generating Public Key:

Select two prime no's. Suppose  $P = 53$  and  $Q = 59$ .

Now First part of the Public key :  $n = P \cdot Q = 3127$ .

We also need a small exponent say  $e$  :

But  $e$  Must be

An integer.

Not be a factor of  $\Phi(n)$ .

$1 < e < \Phi(n)$  [ $\Phi(n)$  is discussed below],

Let us now consider it to be equal to 3.

Our Public Key is made of  $n$  and  $e$

>> Generating Private Key:

We need to calculate  $\Phi(n)$  :

Such that  $\Phi(n) = (P-1)(Q-1)$

$d = (k*\phi(n) + 1) / e$  for some integer  $k$

For  $k = 2$ , value of  $d$  is 2011.

Now we are ready with our – Public Key (  $n = 3127$  and  $e = 3$ ) and Private Key( $d = 2011$ ) Now we will encrypt “**HI**”:

Convert letters to numbers : H = 8 and I = 9

Thus Encrypted Data  $c = (89^e) \bmod n$

Thus our Encrypted Data comes out to be 1394

Now we will decrypt 1394 :

Decrypted Data =  $(c^d) \bmod n$

Thus our Encrypted Data comes out to be 89

8 = H and I = 9 i.e. "HI".

Below is the implementation of the RSA algorithm for

**Method 1:** Encrypting and decrypting small numeral values:

## C++

```
// C program for RSA asymmetric cryptographic
// algorithm. For demonstration values are
// relatively small compared to practical
// application
#include <bits/stdc++.h>
using namespace std;
```

```

{
    int temp;
    while (1) {
        temp = a % h;
        if (temp == 0)
            return h;
        a = h;
        h = temp;
    }
}

// Code to demonstrate RSA algorithm
int main()
{
    // Two random prime numbers
    double p = 3;
    double q = 7;

    // First part of public key:
    double n = p * q;

    // Finding other part of public key.
    // e stands for encrypt
    double e = 2;
    double phi = (p - 1) * (q - 1);
    while (e < phi) {
        // e must be co-prime to phi and
        // smaller than phi.
        if (gcd(e, phi) == 1)
            break;
        else
            e++;
    }

    // Private key (d stands for decrypt)
    // choosing d such that it satisfies
    // d*a = 1 + k * totient
}

```

```

## Java

```

/*package whatever //do not write package name here */
import java.io.*;
import java.math.*;
import java.util.*;
/*
 * Java program for RSA asymmetric cryptographic algorithm.
 * For demonstration, values are
 * relatively small compared to practical application
 */
public class GFG {
    public static double gcd(double a, double h)
    {
        /*

```

```

        double temp;
        while (true) {
            temp = a % h;
            if (temp == 0)
                return h;
            a = h;
            h = temp;
        }
    }
public static void main(String[] args)
{
    double p = 3;
    double q = 7;

    // Stores the first part of public key:
    double n = p * q;

    // Finding the other part of public key.
    // double e stands for encrypt
    double e = 2;
    double phi = (p - 1) * (q - 1);
    while (e < phi) {
        /*
         * e must be co-prime to phi and
         * smaller than phi.
         */
        if (gcd(e, phi) == 1)
            break;
        else
            e++;
    }
    int k = 2; // A constant value
    double d = (1 + (k * phi)) / e;

    // Message to be encrypted
    double msg = 12;
}

```

```

    // Encryption c = (msg ^ e) % n
    double c = Math.pow(msg, e);
    c = c % n;
    System.out.println("Encrypted data = " + c);

    // Decryption m = (c ^ d) % n
    double m = Math.pow(c, d);
    m = m % n;
    System.out.println("Original Message Sent = " + m);
}

}

// This code is contributed by Pranay Arora.

```

## Python3

```

# Python for RSA asymmetric cryptographic algorithm.
# For demonstration, values are
# relatively small compared to practical application
import math

}

// This code is contributed by Pranay Arora.

```

## Javascript

```

//GFG
//Javascript code for this approach
function gcd(a, h) {

```

```
/*
let temp;
while (true) {
    temp = a % h;
    if (temp == 0) return h;
    a = h;
    h = temp;
}
}

let p = 3;
let q = 7;

// Stores the first part of public key:
let n = p * q;

// Finding the other part of public key.
// e stands for encrypt
let e = 2;
let phi = (p - 1) * (q - 1);
while (e < phi) {
    /*
     * e must be co-prime to phi and
     * smaller than phi.
    */
    if (gcd(e, phi) == 1) break;
    else e++;
}
let k = 2; // A constant value
let d = (1 + (k * phi)) / e;

// Message to be encrypted
let msg = 12;

console.log("Message data = " + msg);

// Encryption c = (msg ^ e) % n
```

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

```
console.log("Encrypted data = " + c);

// Decryption m = (c ^ d) % n
let m = Math.pow(c, d);
m = m % n;
console.log("Original Message Sent = " + m);

//This code is written by Sundaram
```

## Output

```
Message data = 12.000000
Encrypted data = 3.000000
Original Message Sent = 12.000000
```

**Method 2:** Encrypting and decrypting plain text messages containing alphabets and numbers using their ASCII value:

## C++

```
#include <bits/stdc++.h>
using namespace std;
set<int>
```

```
int private_key;
int n;
// we will run the function only once to fill the set of
// prime numbers
void primefiller()
{
    // method used to fill the primes set is seive of
    // eratosthenes(a method to collect prime numbers)
    vector<bool> seive(250, true);
    seive[0] = false;
    seive[1] = false;
    for (int i = 2; i < 250; i++) {
        for (int j = i * 2; j < 250; j += i) {
            seive[j] = false;
        }
    } // filling the prime numbers
    for (int i = 0; i < seive.size(); i++) {
        if (seive[i])
            prime.insert(i);
    }
}
// picking a random prime number and erasing that prime
// number from list because p!=q
int pickrandomprime()
{
    int k = rand() % prime.size();
    auto it = prime.begin();
    while (k--)
        it++;
    int ret = *it;
    prime.erase(it);
    return ret;
}
void setkeys()
{
    int prime1 = pickrandomprime(); // first prime number
    int prime2 = pickrandomprime(); // second prime number
```

```

n = prime1 * prime2;
int fi = (prime1 - 1) * (prime2 - 1);
int e = 2;
while (1) {
    if (__gcd(e, fi) == 1)
        break;
    e++;
} // d = (k*Φ(n) + 1) / e for some integer k
public_key = e;
int d = 2;
while (1) {
    if ((d * e) % fi == 1)
        break;
    d++;
}
private_key = d;
}
// to encrypt the given number
long long int encrypt(double message)
{
    int e = public_key;
    long long int encrpyted_text = 1;
    while (e--) {

## Output

Initial message:

Test Message

The encoded message(encrypted by public key)

863312887135951593413927434912887135951359583051879012887

The decoded message(decrypted by private key)

Test Message

## Implementation of RSA Cryptosystem using Primitive Roots in C++

we will implement a simple version of RSA using primitive roots.

### Step 1: Generating Keys

To start, we need to generate two large prime numbers, p and q. These primes should be of roughly equal length and their product should be much larger than the message we want to encrypt.

We can generate the primes using any primality testing algorithm, such as the Miller-Rabin test. Once we have the two primes, we can compute their product  $n = p \cdot q$ , which will be the modulus for our RSA system.

Next, we need to choose an integer e such that  $1 < e < \phi(n)$  and  $\gcd(e, \phi(n)) = 1$ , where  $\phi(n) = (p-1)*(q-1)$  is Euler's totient function. This value of e will be the public key exponent.

To compute the private key exponent d, we need to find an integer d such that  $d \cdot e = 1 \pmod{\phi(n)}$ . This can be done using the extended Euclidean algorithm.

Our public key is  $(n, e)$  and our private key is  $(n, d)$ .

### Step 2: Encryption

To encrypt a message m, we need to convert it to an integer between 0 and  $n-1$ . This can be done using a reversible encoding scheme, such as ASCII or UTF-8.

Once we have the integer representation of the message, we compute the ciphertext c as  $c = m^e \pmod{n}$ . This can be done efficiently using modular exponentiation algorithms, such as binary exponentiation.

### Step 3: Decryption

To decrypt the ciphertext c, we compute the plaintext m as  $m = c^d \pmod{n}$ . Again, we can use modular exponentiation algorithms to do this efficiently.

### Step 4: Example

Let's walk through an example using small values to illustrate how the RSA cryptosystem works.

Suppose we choose  $p = 11$  and  $q = 13$ , giving us  $n = 143$  and  $\phi(n) = 120$ . We can choose  $e = 7$ , since  $\gcd(7, 120) = 1$ . Using the extended Euclidean algorithm, we can compute  $d = 103$ , since  $7 \cdot 103 = 1 \pmod{120}$ .

Our public key is  $(143, 7)$  and our private key is  $(143, 103)$ .

Suppose we want to encrypt the message "HELLO". We can convert this to the integer 726564766, using ASCII encoding. Using the public key, we compute the ciphertext as  $c = 726564766^7 \pmod{143} = 32$ .

To decrypt the ciphertext, we use the private key to compute  $m = 32^{103} \pmod{143} = 726564766$ , which is the original message.

## C++

```
#include <iostream>
#include <cmath>
using namespace std;

// calculate phi(n) for a given number n
int phi(int n) {
    int result = n;
    for (int i = 2; i <= sqrt(n); i++) {
        if (n % i == 0) {
            while (n % i == 0) {
                n /= i;
            }
            result -= result / i;
        }
    }
    if (n > 1) {
        result -= result / n;
    }
    return result;
}

// calculate gcd(a, b) using the Euclidean algorithm
int gcd(int a, int b) {
    if (b == 0) {
        return a;
    }
    return gcd(b, a % b);
}

// calculate a^b mod m using modular exponentiation
int modpow(int a, int b, int m) {
    int result = 1;
    while (b > 0) {
```

```

        a = (a * a) % m;
        b >>= 1;
    }
    return result;
}

// generate a random primitive root modulo n
int generatePrimitiveRoot(int n) {
    int phiN = phi(n);
    int factors[phiN], numFactors = 0;
    int temp = phiN;
    // get all prime factors of phi(n)
    for (int i = 2; i <= sqrt(temp); i++) {
        if (temp % i == 0) {
            factors[numFactors++] = i;
            while (temp % i == 0) {
                temp /= i;
            }
        }
    }
    if (temp > 1) {
        factors[numFactors++] = temp;
    }
    // test possible primitive roots
    for (int i = 2; i <= n; i++) {
        bool isRoot = true;
        for (int j = 0; j < numFactors; j++) {
            if (modpow(i, phiN / factors[j], n) == 1) {
                isRoot = false;
                break;
            }
        }
        if (isRoot) {
            return i;
        }
    }
    return -1;
}

```

```
int main() {
    int p = 61;
    int q = 53;
    int n = p * q;
    int phiN = (p - 1) * (q - 1);
    int e = generatePrimitiveRoot(phiN);
    int d = 0;
    while ((d * e) % phiN != 1) {
        d++;
    }
    cout << "Public key: {" << e << ", " << n << "}" << endl;
    cout << "Private key: {" << d << ", " << n << "}" << endl;
    int m = 123456;
    int c = modpow(m, e, n);
    int decrypted = modpow(c, d, n);
    cout << "Original message: " << m << endl;
    cout << "Encrypted message: " << c << endl;
    cout << "Decrypted message: " << decrypted << endl;
    return 0;
}
```

Output:

```
Public key: {3, 3233}
Private key: {2011, 3233}
Original message: 123456
Encrypted message: 855
Decrypted message: 123456
```

- **Security:** RSA algorithm is considered to be very secure and is widely used for secure data transmission.
- **Public-key cryptography:** RSA algorithm is a public-key cryptography algorithm, which means that it uses two different keys for encryption and decryption. The public key is used to encrypt the data, while the private key is used to decrypt the data.
- **Key exchange:** RSA algorithm can be used for secure key exchange, which means that two parties can exchange a secret key without actually sending the key over the network.
- **Digital signatures:** RSA algorithm can be used for digital signatures, which means that a sender can sign a message using their private key, and the receiver can verify the signature using the sender's public key.
- **Speed:** The RSA technique is suited for usage in real-time applications since it is quite quick and effective.
- **Widely used:** Online banking, e-commerce, and secure communications are just a few fields and applications where the RSA algorithm is extensively developed.

### Disadvantages:

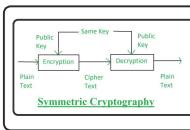

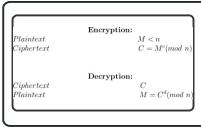

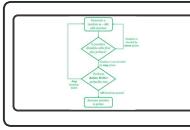

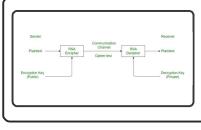

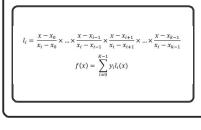

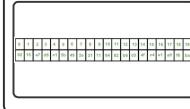

- **Slow processing speed:** RSA algorithm is slower than other encryption algorithms, especially when dealing with large amounts of data.
- **Large key size:** RSA algorithm requires large key sizes to be secure, which means that it requires more computational resources and storage space.
- **Vulnerability to side-channel attacks:** RSA algorithm is vulnerable to side-channel attacks, which means an attacker can use information leaked through side channels such as power consumption, electromagnetic radiation, and timing analysis to extract the private key.
- **Limited use in some applications:** RSA algorithm is not suitable for some applications, such as those that require constant encryption and decryption of large amounts of data, due to its slow processing speed.
- **Complexity:** The RSA algorithm is a sophisticated mathematical technique that some individuals may find challenging to comprehend and use.
- **Key Management:** The secure administration of the private key is necessary for the RSA algorithm, although in some cases this can be difficult.

Whether you're preparing for your first job interview or aiming to upskill in this ever-evolving tech landscape, [GeeksforGeeks Courses](#) are your key to success.
